[57] ABSTRACT

A method for treating mammals suffering from conditions associated with excess phospholipase A₂ activity and/or production comprising administering to the mammal an effective amount of a non-antimicrobial tetracycline sufficient to inhibit excess phospholipase A₂ activity and/or production is disclosed.

FIG-1

FIG-2

INHIBITION OF EXCESSIVE PHOSPHOLIPASE A₂ ACTIVITY AND/OR PRODUCTION BY NON-ANTIMICROBIAL TETRACYCLINES

This invention was made with government support under Grant #R37-DE-03987 awarded by The National Institute of Dental Research (NIH). The government has certain rights in the invention.

BACKGROUND OF THE INVENTION

The present application is a continuation-in-part of Ser. No. 08/115,158 filed Aug. 31, 1993, which is a continuation-in-part of Ser. No. 08/025,035, filed on Mar. 2, 1993, now abandoned, both of which are incorporated herein by reference.

The present invention relates to a method of treating mammals suffering from conditions associated with excessive phospholipase A₂ activity and/or production by administering to the mammal an amount and/or a type of a tetracycline that is not effectively antimicrobial but which effectively inhibits excessive phospholipase A₂ activity and/or production. Excessive phospholipase A₂ activity and/or production has been implicated in several disease conditions including: rheumatoid arthritis and other tissue destructive conditions, sepsis, septic shock, multisystem organ failure, pancreatitis, malaria, psoriasis and inflammatory bowel diseases. A composition useful in the treatment of mammals suffering from conditions associated with excessive phospholipase A₂ activity and/or production is provided as well.

Phospholipase A₂ (PLA₂) is a ubiquitous lipolytic enzyme that has been implicated as a possible mediator of inflammation. Pruzanski et al., *Immunol. Today* 12: 143-146 (1991). Specifically, PLA₂ hydrolyses the 2-acetyl position of glycerophospholipids, liberating free-fatty acids, mainly arachidonic acid and lysophosphatides. Granstrom, *Inflammation* 8: S15-25 (1984, suppl 5), O'Flaherty, *Lab. Invest.* 47: 314-329 (1982). Subsequently, it is believed that arachidonic acid is converted into a variety of proinflammatory eicosanoids. Trang, *Semin. Arthritis Rheum.* 9: 153-190 (1980), Williams, *Br. Med. Bull.* 39:239-242 (1983).

As indicated above, one of the suggested mechanisms of inflammation involves the activation of the arachidonic acid cascade which results in the liberation of a variety of proinflammatory eicosanoids. Van den Bosch, *Biochem. Biophys. Acta* 604: 191-246 (1980), Vadas et al., *Lab. Invest.* 55: 391-404 (1986). More recently, it has been suggested that PLA₂ controls the first step in the liberation of arachidonic acid from phospholipids. Vadas et al., *Lab. Invest.* 55: 391-404 (1986). It has also been suggested that the inflammatory process may be conceptualized as a four-stage event: 1) exposure to the injurious agent, 2) synthesis and release of proximal mediators, 3) synthesis and secretion of PLA₂ and 4) synthesis and release of distal effectors. Pruzanski et al., *Immunol. Today* 12: 143-146 (1991).

In stage 1 of this proposed scenario several factors participate in phagocytic and pinocytic activity, while others act as mediators of inflammation.

During stage 2, it is believed that a large number of proinflammatory mediators are synthesized and released in response to an injurious agent. Included in these mediators are complement, proteases, the contact activation system, toxic oxygen radicals, the interleukins (IL) (Mizel, *Faseb J.* 3: 2379-2388 (1989)); tumor necrosis factor (TNF) (Reuter

et al., *New Engl. J. Med.* 316: 379-385 (1987)); interferons (INF) (Nathan et al., in *Inflammation* (Gallin et al. eds.) Raven Press 229-251 (1988)); platelet-activating factor (PAF) (Braquet et al., *Immunol Today* 8: 345-352 (1987)); eicosanoids (Marcus in *Inflammation* (Gallin et al. eds.) Raven Press 129-137 (1988)); and others (Wolpe et al., *FASEB J.* 3: 2565-2573 (1989)).

It is during stage 3 of this proposed scenario, that PLA₂ appears to be synthesized and secreted. At least two forms of PLA₂ have been found in cells. One form is associated with organelle membranes and plasmalemma and the other, a soluble form, is located in lysosomes and probably in cytosol. Hsueh et al., *Nature* 290: 710-713 (1981). The soluble form may be secreted from the cells into intravascular, interstitial or intraarticular compartments. IL-1 and TNF not only activate membrane-bound PLA₂ but also induce the synthesis and extracellular release of soluble PLA₂. Pruzanski et al., *Immunol Today* 12: 143-146 (1991).

It is believed that many disease states and conditions, which exhibit inflammation as part of the immunological process, are associated with elevated levels of PLA₂. Several experimental models, both in vivo and in vitro, demonstrate this possible relationship between elevated PLA₂ levels and inflammation. For example, glycogen-induced peritonitis in rabbits was found to be associated with high levels of soluble PLA₂ in peritoneal exudate fluid. Franson et al., *J. Lipid Res.* 19: 18-23 (1978). A similar PLA₂ was also found in the ascitic fluid of rodents after intraperitoneal injection of casein or zymosan. Gans et al., *Agents Actions* 27: 341-343 (1989). Experimental endotoxic shock is a recognized model of systemic inflammation. In rabbits challenged intravenously with *Escherichia coli* endotoxin, plasma PLA₂ activity rose 11-fold and correlated with the fall in mean arterial blood pressure. Vadas et al., *Can. J. Physiol. Pharmacol.* 61: 561-566 (1983). PLA₂s purified from the venoms of snakes or bees also produce profound hypotension in various species. Marsh et al., *Toxicol.* 18: 427-435 (1980); Huang et al., *Eur. J. Pharmacol.* 118: 139-146 (1985). These data show that bacterial endotoxins induce the intravascular release of PLA₂ which in turn is related to cardiovascular collapse.

The administration of PLA₂ can also induce significant lung injury. This is particularly important in bacterial peritonitis and septic shock which are often complicated by acute lung injury, manifested as the adult respiratory distress syndrome (ARDS). Intravenous infusion of PLA₂ results in decreased compliance, impaired gas exchange, sequestration and infiltration of neutrophils in the pulmonary vascular bed and alveolar spaces. Morgan et al., *Ann. Surg.* 167: 329-335 (1968); Stommer et al., *Klin. Wochenschr.* 67: 171-176 (1989). Intratracheal instillation of PLA₂ induces an intense inflammatory response in rabbit lung. Shaw et al., *Am. J. Pathol.* 91: 517-530 (1978). Therefore, both circulating and locally produced endogenous PLA₂ may contribute to pulmonary inflammatory changes.

PLA₂ is also vasoactive and proinflammatory when administered by other routes. Intradermal injection of PLA₂ induces sustained hyperemia (Vadas et al., *Nature* 293: 583-585 (1981)); and an acute inflammatory infiltrate (Pruzanski et al., *J. Invest. Dermatol.* 86, 380-383 (1986)). Intra-articular administration of PLA₂ in rats causes an acute synovitis after a single injection and synovial lining cell hyperplasia after repeat injections. Vadas et al., *Am. J. Pathol.* 134: 807-811 (1989). Several studies have also documented the induction of edema in mouse and rat footpads after injection of PLA₂. Vishwanath et al., *Inflammation* 12: 549-561 (1988); Cirino et al., *Eur. J.*

Pharmacol. 166: 505-510 (1989). Moreover, extracellular PLA₂ alters the function of phagocytes. Co-incubation of human neutrophils and monocytes with PLA₂ from synovial fluid results in marked superoxide generation and lysosomal enzyme release, but decreased chemotactic responsiveness.

Numerous in vivo studies have also demonstrated the possible correlation between elevated PLA₂ levels and inflammation. High levels of PLA₂ activity have been found in synovial fluid from the inflamed joints of patients with rheumatoid arthritis (RA), psoriasis and osteoarthritis. Pruzanski et al., *J. Rheumatol.* 12: 211-216 (1985). High Levels of extracellular PLA₂ activity are also present in patients with acute bacterial peritonitis. Vadas et al., in *Cell Activation and Signal Initiation* (Dennis et al., eds.) Alan R. Liss 311-316 (1989). Septic shock in humans is consistently associated with a marked rise in serum PLA₂ activity. In retrospective and prospective studies of Gram-negative septic shock, all patients had elevated serum PLA₂ levels during the acute hypotensive phase, which normalized during convalescence. Vadas et al., *Crit. Care Med.* 16: 1-7 (1988). In all patients, serum PLA₂ levels correlated directly with the magnitude and duration of circulatory collapse. Furthermore, serum PLA₂ was consistently elevated and the magnitude of the early increase in PLA₂ was prognostic of the outcome. Serum PLA₂ levels are also correlated with the increased risk of adult respiratory distress syndrome (ARDS) in patients with sepsis. Vadas, *J. Lab. Clin. Med.* 104: 873-881 (1984).

The exoantigens of the malaria parasite, *Plasmodium falciparum*, share common properties with endotoxin (Jakobsen, et al., *Parasite Immunol.* 10: 593-606 (1988)); and the syndrome caused by *P. falciparum* may resemble that of septic shock (Clark, *Lancet* ii: 75-77 (1978)). Serum PLA₂ levels are elevated as much as 1100-fold before anti-malarial therapy.

Increased levels of PLA₂ have also been found in patients suffering from osteoarthritis (OA). Pruzanski, et al., *J. Rheumatol.* 12: 211-216 (1985). Although OA is considered primarily a degenerative process, inflammatory episodes of varying duration are recognized as an integral part of this disease. Ehrlich, in *Osteoarthritis, Diagnosis and Management* (Moskowitz et al., eds.) W. B. Saunders Co. 199-209 (1984); Revell et al., *Ann. Rheum. Dis.* 47: 300-307 (1988). The mechanism of inflammation in OA has not been elucidated, but recently the role of inflammatory mediators has emerged as an important pathogenetic factor. Pelletier et al., *J. Rheumatol.* 16: (Suppl. 19) 27-29 (1989); Shinmei et al., *J. Rheumatol.* 16: (Suppl. 18) 32-34 (1989).

The diseases and conditions discussed above are not meant to be all encompassing. As the mechanisms of other disease processes are elucidated, PLA₂ may be implicated as a possible mediator of the inflammatory response in those diseases as well. What is evident is the presence of elevated PLA₂ levels in the inflammatory process in numerous serious diseases.

In spite of classical therapies for the treatment of the above diseases, the concomitant inflammation associated with excess levels of PLA₂ in these diseases remains a problem. It is apparent therefore that a need exists for therapeutic agents that inhibit the excessive activity and/or production of PLA₂, thereby controlling or eliminating its effect in various disease conditions. The present invention is intended to address this need.

In particular, the present inventors has discovered that the use of certain tetracyclines inhibits the excessive activity and/or production of phospholipase A₂ (PLA₂). In addition,

the tetracyclines of the present invention can be combined with other classical therapeutic agents, such as anti-inflammatory agents or other medications which have been routinely used to treat the specific conditions discussed above. Other classical medications have not been known to function as inhibitors of excessive PLA₂ activity and/or production. In contrast to these other conventional medications, the tetracyclines of the present invention have clearly demonstrated the inhibition of excessive PLA₂ activity and/or production through the use of certain tetracyclines which inhibit the activity and/or production of PLA₂.

Tetracyclines constitute a family of well known natural and synthetic broad spectrum antibiotics. The parent compound, tetracycline, exhibits the following general structure:

The numbering system of the ring nucleus is as follows:

Tetracycline as well as the 5-OH (Tetramycin) and 7-Cl (Aureomycin) derivatives exist in nature, and are well known antibiotics. Natural tetracyclines may be modified without losing their antibiotic properties, although certain elements of the structure must be retained. The modifications that may and may not be made to the basic tetracycline structure have been reviewed by Mitscher in *The Chemistry of Tetracyclines*, Chapter 6, Marcel Dekker, Publishers, N.Y. (1978). According to Mitscher, the substituents at positions 5-9 of the tetracycline ring system may be modified without the complete loss of antibiotic properties. Changes to the basic ring system or replacement of the substituents at positions 1-4 and 10-12, however, generally lead to synthetic tetracyclines with substantially less or effectively no antimicrobial activity. For example, 4-dedimethylaminotetracycline is commonly considered to be a non-antimicrobial tetracycline.

The use of tetracycline antibiotics, while effective, may lead to undesirable side effects. For example, the long term administration of antibiotic tetracyclines may reduce or eliminate healthy flora, such as intestinal flora, and may lead to the production of antibiotic resistant organisms or the overgrowth of opportunistic yeast and fungi.

In addition to their antibiotic properties, tetracyclines have been described for a number of uses. For example, tetracyclines are also known to inhibit the activity of collagen destructive enzymes such as mammalian collagenase, gelatinase, macrophage elastase and bacterial collagenase. Golub et al., *J. Periodont. Res.* 20: 12-23 (1985); Golub et al., *Crit. Revs. Oral Biol. Med.* 2: 297-322 (1991).

Tetracyclines, administered at both antimicrobial levels and non-antimicrobial levels, have been known to play a role in reducing collagenase and other collagenolytic enzyme activity as well as collagen breakdown. U.S. Pat. Nos. 4,666,897; 4,704,383; 4,935,411; 4,935,412. In addition, tetracyclines have been known to inhibit wasting and protein degradation of mammalian skeletal muscle, U.S. Pat. No.

5,045,538. In addition, tetracyclines have been demonstrated to enhance bone formation in osteoporosis, U.S. Pat. No. 4,925,833. We have now discovered that tetracycline exhibits an anti-phospholipase A_2 activity.

U.S. Pat. No. 4,704,383 to McNamara et al. discloses that tetracyclines having substantially no effective antimicrobial activity inhibit collagenolytic enzyme activity in rats. McNamara et al. also report that non-antimicrobial tetracyclines reduce bone resorption in organ culture. Earlier, U.S. Pat. No. 4,666,897 to Golub, et al. disclosed that tetracyclines in general, including commercially-available antimicrobial forms of the drug, inhibit excessive mammalian collagenolytic enzyme activity resulting in decreased connective tissue breakdown including that which occurs during bone resorption.

There have been a number of suggestions that tetracyclines, including non-antimicrobial tetracyclines, are effective in treating arthritis in rats. See, for example, Golub et al., "Tetracyclines (TCs) Inhibit Matrix Metalloproteinases (MMPs): In Vivo Effects In Arthritic And Diabetic Rats, And New In Vitro Studies," *Matrix*, Suppl. No 1: 315-316 (1992); Greenwald et al. "CMT, A Metalloproteinase Inhibitor, Prevents Bone Resorption In Adjuvant Arthritis." *Arthritis Rheum.* 34 (#9 suppl): S66 (abstract #A6), abstract presented at 55th Annual Meeting, Amer. College of Rheumatology, Boston Mass., Nov. 18, 1991; Breedveld, "Suppression Of Collagen And Adjuvant Arthritis By A Tetracycline," Northeastern Regional Meeting Of The Amer. Rheum. Assoc., Atlantic City, N.J., Oct. 23-24, 1987. For a related commentary regarding the effect of non-antimicrobial tetracyclines on bone loss see Sipos et al., "The Effect Of Collagenase Inhibitors On Alveolar Bone Loss Due To Periodontal Disease In Desalivated Rats," abstract presented at Matrix Metalloproteinase Conference, Destin, Fla., Sep. 11-15, 1989.

The effect of tetracyclines has not been firmly established for human patients with rheumatoid arthritis and various studies have indicated contrary results. Thus, Skinner et al., *Arthritis and Rheumatism* 14: 727-732 (1971), reported no significant benefit from tetracycline therapy for human sufferers of rheumatoid arthritis even though Greenwald et al., reported in *J. Rheumatol.* 14: 28-32 (1987) that the oral administration of a tetracycline (minocycline) to humans with severe rheumatoid arthritis decreased the collagenase activity in the joint tissues. More recently, however, Breedveld *J. Rheumat.* 17: 43 (1990) administered to humans, with rheumatoid arthritis, minocycline over a 16 week time period and reported a statistically significant improvement in a number of parameters of this disease, e.g. grip strength, erythrocyte sedimentation rate, etc. However, this study was not a placebo-controlled double blind study.

The use of tetracyclines in combination with non-steroidal anti-inflammatory agents has been studied in the treatment of inflammatory skin disorders caused by acne vulgaris. Wong et al., *Journal of American Academy of Dermatology* 11: 1076-1081 (1984), studied the combination of tetracycline and ibuprofen and reported that tetracycline was an effective agent against acne vulgaris, while ibuprofen was useful in reducing the resulting inflammation by inhibition of cyclooxygenase. Funt, *Journal of the American Academy of Dermatology* 13: 524-525 (1985), disclosed similar results by combining anti-microbial doses of minocycline and ibuprofen.

Based on the foregoing, tetracyclines, including their chemically modified analogs, have been found to be effective in different treatments. However, there has been no

suggestion or indication that chemically modified tetracyclines inhibit excessive PLA_2 activity and/or production.

The present invention is intended to provide a means for inhibiting the excessive PLA_2 activity and/or production associated with many disease states. The present invention demonstrates that chemically modified analogs of tetracycline, which have lost their antimicrobial efficacy, have a novel new use, that is, the ability to inhibit excessive PLA_2 activity and/or production. This non-antimicrobial property of tetracyclines reduces the severe inflammatory complications associated with excessive PLA_2 activity and/or production present in many disease states.

SUMMARY OF THE INVENTION

The present invention provides a method for treating mammals suffering from conditions associated with excess phospholipase A_2 activity and/or production which includes administering to the mammal an amount and/or type of a tetracycline which inhibits the excess PLA_2 activity and/or production but which is non-antimicrobial. Non-limiting examples of conditions or diseases associated with excess PLA_2 activity and/or production include rheumatoid arthritis, other tissue-destructive conditions, sepsis, septic shock, pancreatitis, malaria, psoriasis, inflammatory bowel diseases and multisystem organ failure among others.

Chemically-modified non-antimicrobial tetracyclines, for example dedimethylaminotetracyclines are useful in the present invention. Dedimethylaminotetracyclines include 4-dedimethylaminotetracycline, 4-dedimethylamino-5-oxetetracycline, 4-dedimethylamino-7-chlorotetracycline, 4-hydroxy-4-dedimethylaminotetracycline, 5a,6-anhydro-4-hydroxy-4-dedimethylaminotetracycline, 6 α -deoxy-5-hydroxy-4-dedimethylaminotetracycline, 6-demethyl-6-deoxy-4-dedimethylaminotetracycline, 4-dedimethylamino-12a-deoxytetracycline, 4-dedimethylamino-11-hydroxy-12a-deoxytetracycline and 4-dedimethylamino-7-dimethylaminotetracycline.

Further examples of chemically-modified tetracyclines useful in the present invention are 6a-benzylthiomethyltetracycline, the 2-nitro analogs of tetracycline, the mono-N-alkylated amide of tetracycline, 6-fluoro-6-demethyltetracycline, 11a-chlorotetracycline and 12a-deoxytetracycline and its derivatives. The tetracyclines may be coupled with a pharmaceutically acceptable carrier.

The present invention also provides a method for treating mammals suffering from conditions associated with excess phospholipase A_2 activity and/or production which includes the administration to the mammal of (i) an amount and/or type of a tetracycline that effectively inhibits excess PLA_2 activity and/or production and (ii) an amount of a classical therapeutic agent which, when combined with the effectively anti- PLA_2 amount and/or type of tetracycline, results in a significant reduction in tissue destruction.

The invention further provides a pharmaceutical composition for treating mammals suffering from conditions associated with excess phospholipase A_2 activity and/or production which includes a) an amount and/or type of a tetracycline that effectively inhibits PLA_2 activity and/or production and b) a classical therapeutic agent which, when combined with the effectively anti-phospholipase A_2 amount of tetracycline, results in a significant reduction in tissue destruction.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a graphic representation of assay measurements demonstrating the inhibition of recombinant human PLA_2

by the inventive tetracyclines as compared to those which show little or no PLA₂ inhibition.

FIG. 2 is a graphic representation of assay measurements demonstrating the inhibition of recombinant human PLA₂ by 4-dedimethylamino-7-dimethylaminotetracycline (CMT-10).

DETAILED DESCRIPTION OF THE INVENTION

It has been discovered that the use of certain tetracyclines inhibits the activity and/or production of PLA₂. While not wishing to be bound by any one theory, it is believed that the tetracyclines of the present invention bind to PLA₂ in such a way as to inhibit PLA₂'s ability to bind to its substrate. Alternatively, the tetracyclines of the present invention may bind to the PLA₂ substrate in such a way as to inhibit the substrate's ability to bind to PLA₂. As previously mentioned, conditions associated with excess PLA₂ activity and/or production which are treated in accordance with the present invention include (but are not limited to) rheumatoid and other inflammatory arthritides, other tissue-destructive conditions, sepsis, septic shock, pancreatitis, malaria, psoriasis, inflammatory bowel diseases and multisystem organ failure. Tissue destructive conditions may include Behcet's syndrome, Reiter's syndrome, Kawasaki disease, osteoarthritis and psoriatic conditions. The conditions treated by the present invention occur in mammals. Mammals include, for example, humans and laboratory animals such as rabbits, mice and rats.

The tetracyclines of the present invention can be combined with classical therapeutic agents. While the tetracycline inhibits excess PLA₂ activity and/or production, the classical therapeutic agent ameliorates the disease or condition through a separate mode of action.

The tetracyclines of the present invention are administered in an amount sufficient to effectuate the inhibition of PLA₂ activity and/or production. The amount of tetracycline used in the present invention is that which is effectively non-antimicrobial in the patient. Thus, tetracyclines generally used for their antimicrobial properties can also be used herein in doses which are effectively non-antimicrobial.

A classical therapeutic agent is a medication, treatment or therapy that is considered the standard course of action or is the medication, treatment or therapy of choice when treating a particular condition. For example, anti-inflammatory agents are routinely used in the treatment of rheumatoid arthritis and other tissue-destructive conditions.

The tetracyclines useful in the present invention may be any tetracycline administered to a mammal in a dose that is effectively non-antimicrobial in the mammal. Preferably, the tetracycline is modified so as to reduce its antimicrobial properties. Methods for reducing the antimicrobial properties of a tetracycline are disclosed in "The Chemistry of the Tetracyclines", Chapter 6, Mitscher, Marcel Dekker, Publishers, N.Y. (1978) at page 211. As pointed out by Mitscher, modification at positions 1, 2, 3, 4, 10 and 12a lead to loss of antimicrobial bioactivity. Non-antimicrobial tetracyclines are preferred since they can be used at therapeutic levels which impart fewer side effects than antimicrobial tetracyclines at the same dosage level.

The preferred tetracyclines are those that lack the dimethylamino group at position 4. Such chemically modified tetracyclines include, for example, 4-dedimethylaminotetracycline, 4-dedimethylamino-5-oxytetracycline, 4-dedimethylamino-7-chlorotetracycline, 4-hydroxy-4-dedimethyl-

aminotetracycline, 5a,6-anhydro-4-hydroxy-4-dedimethylaminotetracycline, 6-demethyl-6-deoxy-4-dedimethylaminotetracycline, 4-dedimethylamino-11-hydroxy-12a-deoxytetracycline, 6a-deoxy-5-hydroxy-4-dedimethylaminotetracycline, 4-dedimethylamino-7-dimethylaminotetracycline, 4-dedimethylamino-12a-deoxytetracycline and its derivatives. Tetracyclines altered at the 2 carbon position to produce a nitrile, e.g., tetracyclinonitrile may be useful as non-antimicrobial agents exhibiting anti-PLA₂ activity when administered via non-oral routes.

Further examples of tetracyclines modified for reduced antimicrobial activity include 6a-benzylthiomethylenetetracycline, the mono-N-alkylated amide of tetracycline, 6-fluoro-6-demethyltetracycline, 11a-chlorotetracycline and 12a-deoxytetracycline and its derivatives. However, the pyrazole derivative of tetracycline is inactive.

The effective amount of tetracycline is that which is effectively anti-PLA₂ while not effectively antimicrobial. For purposes of this invention, a tetracycline is effectively anti-PLA₂ if it is present in an amount which significantly reduces excess PLA₂ activity and/or production. For purposes of the present invention, excess PLA₂ activity and/or production is defined as that which induces local or systemic inflammation and or connective tissue breakdown.

A tetracycline is considered effectively non-antimicrobial if it does not significantly prevent the growth of microbes. This of course may vary depending upon a number of factors, such as, type of tetracycline, disease state and type of microbe. The maximal useful dosage for humans is the highest dosage that does not cause adverse side effects. For the purpose of the present invention, side effects include clinically significant antimicrobial activity, as well as toxic effects. For example, a dose in excess of about 50 mg/kg/day would likely produce side effects in most mammals, including humans.

The preferred pharmaceutical composition for use in the present invention comprises a combination of the tetracycline and a classical therapeutic agent in a suitable pharmaceutical carrier. The means of delivery of the pharmaceutical carrier with the active agent may be in a variety of forms including capsules, compressed tablets, pills, solutions or suspensions. It is contemplated that carriers be included which are suitable for administration orally, topically, by injection and by other selected means.

EXAMPLES

The following Example serves to provide further appreciation of the invention but is not meant in any way to restrict the effective scope of the invention.

Example 1

Six different chemically-modified tetracyclines, including CMT-1 (4-dedimethylaminotetracycline), CMT-2 (tetracyclinonitrile), CMT-3 (6-demethyl-6-deoxy-4-dedimethylaminotetracycline), CMT-4 (4-de-dimethylamino-7-chlorotetracycline), CMT-5 (pyrazole analog) and CMT-6 (4-hydroxy-4-dedimethylaminotetracycline), were examined for their ability to inhibit PLA₂ activity in vitro. The sources of PLA₂ that were tested included recombinant human PLA₂, human pancreatic and porcine pancreatic PLA₂ and Naja naja PLA₂. The CMTs were dissolved in water and NaOH and the pH was subsequently reduced to pH 7.3-7.6 by the addition of acid. Various concentrations of CMTs, ranging from 5-100 µg/ml, were preincubated with

the different PLA₂ enzymes for 30 minutes and the mixture was tested for PLA₂ activity using a known *E. coli* assay method (see *Arthritis and Rheumatism*, 34 Supp. 9: p. S160 (abst C167)).

Results

FIG. 1 is a graphic representation of the assay data for the different CMTs which were incubated with recombinant human PLA₂. At a final concentration of 5 and 10 µg/ml, none of the CMTs tested (CMTs 1-6) showed substantial inhibition of PLA₂ activity. At concentrations of 25 µg/ml or greater, CMT-1, CMT-3, CMT-4 and CMT-6 all exhibited significant PLA₂-inhibitory activity. However, even at the highest concentrations tested, CMT-2 and CMT-5 lacked any PLA₂-inhibitory activity.

Therefore, selected CMT's, not all members of this category of drugs, inhibit PLA₂ activity in vitro.

Table 1 lists the IC₅₀ of the various CMTs. The IC₅₀ is the concentration of the drug (CMT) required to inhibit 50% of the enzyme being tested (PLA₂).

TABLE 1

Drug	IC ₅₀
CMT-1	37 µg/ml
CMT-3	28 µg/ml
CMT-4	42 µg/ml
CMT-6	17 µg/ml

It should be noted that CMT-1, 3, 4 and 6 also were found to inhibit human pancreatic and porcine pancreatic PLA₂.

Example 2

A chemically-modified tetracycline, 4-dedimethylamino-7-dimethylaminotetracycline (CMT-10), was examined for its ability to inhibit PLA₂ activity in vitro. The sources of PLA₂ that were tested included were recombinant human PLA₂ (snPLA₂), human pancreatic and porcine pancreatic PLA₂ and Naja naja PLA₂. CMT-10 was dissolved in water and NaOH and the pH was subsequently reduced to pH 7.3-7.6 by the addition of acid. Various concentrations of CMT-10, ranging from 5-100 µg/ml, were preincubated with the different PLA₂ enzymes for 30 minutes and the mixture was tested for PLA₂ activity using a known *E. coli* assay method (see *Arthritis and Rheumatism*, 34 Supp. 9: p. S160 (abst C167)).

In particular, [¹⁴C]Oleic acid-labelled *Escherichia coli* (strain K12 C600) were used as the substrate. This substrate has been characterized with respect to phospholipid composition and distribution of radiolabel. Reaction mixtures contained 10 mg bovine serum albumin, 2 mM CaCl₂, 2.8×10⁸ radiolabelled *E. coli* and 0.1M Tris-HCl buffer, pH 7.5 in a total volume of 1.5 ml. Reaction mixtures were incubated at 37° C. for 30 min. The reaction was terminated by filtration through a 0.45 µm Millipore filter, thereby retaining unhydrolysed *E. coli* membranes, and allowing the [¹⁴C]oleic acid bound to the BSA carrier, released as a result of PLA₂ hydrolysis, to pass through the filter. Assays were performed in duplicate and values shown represent the mean of two determinations with a SD<5% of the mean. Assays were performed in substrate excess and enzyme activities were corrected for non-enzymatic hydrolysis. One unit of PLA₂ activity is defined as the hydrolysis of 56 pmol of phospholipid substrate (representing 1% of total *E. coli* phospholipid) in 30 min at 37° C.

Results

FIG. 2 is a graphic representation of the assay data for 4-dedimethylamino-7-dimethylaminotetracycline (CMT-10) which was incubated with recombinant human PLA₂. At a final concentration of 5 and 10 µg/ml, CMT-10 did not exhibit substantial inhibition of PLA₂ activity. At concentrations of 25 µg/ml or greater, CMT-10, exhibited significant PLA₂-inhibitory activity. Table 2 is a tabular representation of the information found in FIG. 2.

TABLE 2

INHIBITION OF RECOMBINANT HUMAN snPLA ₂ BY CMT-10	
CONCENTRATION OF CMT-10 (µg/ml)	% OF INHIBITION
5	4 ± 4
10	12 ± 2
25	45 ± 1
50	75 ± 2
100	87 ± 2

The IC₅₀ of CMT-10 is 30 µg/ml. The IC₅₀ is the concentration of the drug, CMT-10, required to inhibit 50% of the enzyme activity (PLA₂). It should be noted that CMT-10 was also found to inhibit human pancreatic PLA₂. A concentration of 30 µg/ml CMT-10 exhibited 66% inhibition.

These experimental results demonstrate a powerful new medical tool for preventing excessive PLA₂ activity and/or production which is believed to be responsible for the serious tissue destruction associated with many disease states and conditions.

Thus, while there has been described what are presently believed to be the preferred embodiments of the invention, those skilled in the art will understand that other and further modifications can be made without departing from the spirit of the invention. It is intended that the present invention includes all such modifications as come within the true scope of the invention as set forth in the claims.

What is claimed is:

1. A method for treating conditions associated with excess phospholipase A₂ activity and/or production in a mammal comprising administering to the mammal an amount of a non-antimicrobial tetracycline sufficient to inhibit said excess phospholipase A₂ activity and/or production;

wherein the excess phospholipase A₂ is present in the inflammatory process associated with sepsis, septic shock, pancreatitis, psoriasis, inflammatory bowel diseases or multisystem organ failure; and

wherein the non-antimicrobial tetracycline is a dedimethylaminotetracycline.

2. The method of claim 1, wherein the dedimethylaminotetracycline is selected from the group consisting of 4-dedimethylaminotetracycline, 4-dedimethylamino-5-oxytetracycline, 4-dedimethylamino-7-chlorotetracycline, 5a,6-anhydro-4-hydroxy-4-dedimethylaminotetracycline, 6-demethyl-6-deoxy-4-dedimethylaminotetracycline, 6α-deoxy-5-hydroxy-4-dedimethylaminotetracycline and 4-dedimethylamino-12a-deoxytetracycline and 4-dedimethylamino-11-hydroxy-12a-deoxytetracycline.

3. The method of claim 1, wherein the tetracycline is in a pharmaceutically acceptable carrier.
